Quick tip for anyone building a career in Tech

#career #development

If you're growing in the tech field, make sure you have **public and relevant projects** on your GitHub.

And when I say "relevant," I'm not talking about complex enterprise systems —

complete study projects are perfectly fine, such as:

- Well-structured APIs
- Functional frontend applications
- Small full-stack apps
- Tools that solve real problems
- Project templates and boilerplates

In other words: something that shows **your technical maturity**, not just random bootcamp exercises or generic CRUDs thrown together.

These projects help recruiters and tech leads understand:

- How you structure an application
- Your architectural thinking
- Whether you apply industry best practices
- Your awareness of security
- Your ability to document your work
- Code clarity and consistency
- How you make technical decisions

When I used to review candidates, I checked all of this.

And professionals who ignored these details **lost points in the evaluation**, even if they were technically strong.

“But AI can generate all the code now.”

Yes, AI helps a lot.

But here are two important truths:

1) AI will not do everything for you — especially when it comes to deep understanding, technical reasoning, and decision-making.

Not to mention the situations where AI generates way more code than necessary.

2) It’s easy to spot AI-generated code that wasn’t reviewed, or when a developer can’t explain what they built.

And let’s be honest: even *before* AI, many people were copying code or entire projects without understanding them.

The problem is **not using AI**.

The problem is using it without reviewing, without understanding, and without developing real critical thinking.

If you want to stand out:

👉 publish complete, meaningful projects

👉 review your code (AI-generated or not)

👉 demonstrate technical maturity in practice

👉 build a portfolio that truly represents your skills

Trust me: it makes a huge difference.
